Introduction to Stochastic Finance with Market Examples

Second Edition

Chapman & Hall/CRC FINANCIAL MATHEMATICS SERIES

Introduction to Stochastic Finance with Market Examples

Second Edition

Introduction to Stochastic Finance with Market Examples, Second Edition presents an introduction to pricing and hedging in discrete and continuous-time financial models, emphasizing both analytical and probabilistic methods. It demonstrates both the power and limitations of mathematical models in finance, covering the basics of stochastic calculus for finance, and details the techniques required to model the time evolution of risky assets. The book discusses a wide range of classical topics including Black–Scholes pricing, American options, derivatives, term structure modeling, and change of numéraire. It also builds up to special topics, such as exotic options, stochastic volatility, and jump processes.

New to this Edition

- New chapters on Barrier Options, Lookback Options, Asian Options, Optimal Stopping Theorem, and Stochastic Volatility
- Contains over 235 exercises and 16 problems with complete solutions available online from the instructor resources at <https://bit.ly/3DCvPtm>
- Added over 150 graphs and figures, for more than 250 in total, to optimize presentation
- 57 R coding examples now integrated into the book for implementation of the methods
- Substantially class-tested, so ideal for course use or self-study

With abundant exercises, problems with complete solutions, graphs and figures, and R coding examples, the book is primarily aimed at advanced undergraduate and graduate students in applied mathematics, financial engineering, and economics. It could be used as a course text or for self-study and would also be a comprehensive and accessible reference for researchers and practitioners in the field.

Nicolas Privault received a PhD degree from the University of Paris VI, France. He was with the University of Evry, France, the University of La Rochelle, France, and the University of Poitiers, France. He is currently a Professor with the School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore. His research interests are in the areas of stochastic analysis and its applications.

Chapman & Hall/CRC Financial Mathematics Series

Aims and scope:

The field of financial mathematics forms an ever-expanding slice of the financial sector. This series aims to capture new developments and summarize what is known over the whole spectrum of this field. It will include a broad range of textbooks, reference works, and handbooks that are meant to appeal to both academics and practitioners. The inclusion of numerical code and concrete real-world examples is highly encouraged.

Preface	ix
Introduction	1
1 Assets, Portfolios, and Arbitrage	15
1.1 Portfolio Allocation and Short Selling	15
1.2 Arbitrage	17
1.3 Risk-Neutral Probability Measures	21
1.4 Hedging of Contingent Claims	25
1.5 Market Completeness	27
1.6 Example: Binary Market	27
Exercises	34
2 Discrete-Time Market Model	39
2.1 Discrete-Time Compounding	39
2.2 Arbitrage and Self-Financing Portfolios	41
2.3 Contingent Claims	47
2.4 Martingales and Conditional Expectations	50
2.5 Market Completeness and Risk-Neutral Measures	54
2.6 The Cox–Ross–Rubinstein (CRR) Market Model	56
Exercises	60
3 Pricing and Hedging in Discrete Time	65
3.1 Pricing Contingent Claims	65
3.2 Pricing Vanilla Options in the CRR Model	69
3.3 Hedging Contingent Claims	74
3.4 Hedging Vanilla Options	75
3.5 Hedging Exotic Options	83
3.6 Convergence of the CRR Model	89
Exercises	94
4 Brownian Motion and Stochastic Calculus	113
4.1 Brownian Motion	113
4.2 Three Constructions of Brownian Motion	115
4.3 Wiener Stochastic Integral	118
4.4 Itô Stochastic Integral	126
4.5 Stochastic Calculus	132
Exercises	142

5	Continuous-Time Market Model	153
5.1	Asset Price Modeling	153
5.2	Arbitrage and Risk-Neutral Measures	154
5.3	Self-Financing Portfolio Strategies	156
5.4	Two-Asset Portfolio Model	159
5.5	Geometric Brownian Motion	164
	Exercises	167
6	Black–Scholes Pricing and Hedging	173
6.1	The Black–Scholes PDE	173
6.2	European Call Options	177
6.3	European Put Options	183
6.4	Market Terms and Data	187
6.5	The Heat Equation	190
6.6	Solution of the Black–Scholes PDE	194
	Exercises	197
7	Martingale Approach to Pricing and Hedging	207
7.1	Martingale Property of the Itô Integral	207
7.2	Risk-Neutral Probability Measures	211
7.3	Change of Measure and the Girsanov Theorem	215
7.4	Pricing by the Martingale Method	217
7.5	Hedging by the Martingale Method	223
	Exercises	228
8	Stochastic Volatility	249
8.1	Stochastic Volatility Models	249
8.2	Realized Variance Swaps	252
8.3	Realized Variance Options	256
8.4	European Options – PDE Method	263
8.5	Perturbation Analysis	269
	Exercises	273
9	Volatility Estimation	277
9.1	Historical Volatility	277
9.2	Implied Volatility	279
9.3	Local Volatility	285
9.4	The VIX [®] Index	290
	Exercises	295
10	Maximum of Brownian Motion	299
10.1	Running Maximum of Brownian Motion	299
10.2	The Reflection Principle	300
10.3	Density of the Maximum of Brownian Motion	304
10.4	Average of Geometric Brownian Extrema	313
	Exercises	320

11 Barrier Options	323
11.1 Options on Extrema	323
11.2 Knock-Out Barrier	327
11.3 Knock-In Barrier	337
11.4 PDE Method	340
11.5 Hedging Barrier Options	344
Exercises	345
12 Lookback Options	349
12.1 The Lookback Put Option	349
12.2 PDE Method	351
12.3 The Lookback Call Option	356
12.4 Delta Hedging for Lookback Options	363
Exercises	368
13 Asian Options	371
13.1 Bounds on Asian Option Prices	371
13.2 Hartman–Watson Distribution	377
13.3 Laplace Transform Method	380
13.4 Moment Matching Approximations	380
13.5 PDE Method	386
Exercises	395
14 Optimal Stopping Theorem	401
14.1 Filtrations and Information Flow	401
14.2 Submartingales and Supermartingales	401
14.3 Optimal Stopping Theorem	404
14.4 Drifted Brownian Motion	410
Exercises	415
15 American Options	419
15.1 Perpetual American Put Options	419
15.2 PDE Method for Perpetual Put Options	424
15.3 Perpetual American Call Options	428
15.4 Finite Expiration American Options	431
15.5 PDE Method with Finite Expiration	434
Exercises	438
16 Change of Numéraire and Forward Measures	449
16.1 Notion of Numéraire	449
16.2 Change of Numéraire	451
16.3 Foreign Exchange	460
16.4 Pricing Exchange Options	467
16.5 Hedging by Change of Numéraire	469
Exercises	472
17 Short Rates and Bond Pricing	479
17.1 Vasicek Model	479
17.2 Affine Short Rate Models	485
17.3 Zero-Coupon and Coupon Bonds	488
17.4 Bond Pricing PDE	491
Exercises	503

18 Forward Rates	513
18.1 Construction of Forward Rates	513
18.2 LIBOR/SOFR Swap Rates	522
18.3 The HJM Model	526
18.4 Yield Curve Modeling	530
18.5 Two-Factor Model	534
18.6 The BGM Model	537
Exercises	538
19 Pricing of Interest Rate Derivatives	543
19.1 Forward Measures and Tenor Structure	543
19.2 Bond Options	546
19.3 Caplet Pricing	548
19.4 Forward Swap Measures	553
19.5 Swaption Pricing	555
Exercises	560
20 Stochastic Calculus for Jump Processes	565
20.1 The Poisson Process	565
20.2 Compound Poisson Process	571
20.3 Stochastic Integrals and Itô Formula with Jumps	576
20.4 Stochastic Differential Equations with Jumps	585
20.5 Girsanov Theorem for Jump Processes	589
Exercises	595
21 Pricing and Hedging in Jump Models	601
21.1 Fitting the Distribution of Market Returns	601
21.2 Risk-Neutral Probability Measures	608
21.3 Pricing in Jump Models	609
21.4 Exponential Lévy Models	611
21.5 Black–Scholes PDE with Jumps	614
21.6 Mean-Variance Hedging with Jumps	616
Exercises	619
22 Basic Numerical Methods	623
22.1 Discretized Heat Equation	623
22.2 Discretized Black–Scholes PDE	626
22.3 Euler Discretization	628
22.4 Milshtein Discretization	629
Exercises	630
Bibliography	631
Index	643

Preface

This book is an introduction to a wide range of topics in financial mathematics, including Black–Scholes pricing, exotic and American options, term structure modeling and change of numéraire, stochastic volatility, and models with jumps. It presents the mathematics of pricing and hedging in discrete and continuous-time financial models, with an emphasis on the complementarity between analytical and probabilistic methods. The contents are mostly mathematical and also aim at making the reader aware of both the power and limitations of mathematical models in finance, by taking into account their conditions of applicability. The text is targeted at the advanced undergraduate and graduate levels in applied mathematics, financial engineering, and economics. It contains 235 exercises and 16 problems, as well as 19 tables and 255 figures, and includes 57 R coding examples for illustrations based on market data.

The point of view adopted is that of mainstream mathematical finance, in which the computation of fair prices is based on the absence of arbitrage hypothesis, therefore excluding riskless profit based on arbitrage opportunities and basic (buying low/selling high) trading. Similarly, this document is not concerned with any “prediction” of stock price behaviors that belong to other domains such as technical analysis, which should not be confused with the statistical modeling of asset prices.

The descriptions of the asset model, self-financing portfolios, arbitrage, and market completeness, are first given in [Chapter 1](#) in a simple two time-step setting. These notions are then reformulated in discrete time in [Chapter 2](#). Here, the impossibility to access future information is formulated using the notion of adapted processes, which will play a central role in the construction of stochastic calculus in continuous time.

In order to trade efficiently, it would be useful to have a formula to estimate the “fair price” of a given risky asset, helping for example to determine whether the asset is undervalued or overvalued at a given time. Although such a formula is not available, we can instead derive formulas for the pricing of options that can act as insurance contracts to protect their holders against adverse changes in the prices of risky assets. The pricing and hedging of options in discrete time, particularly in the fundamental example of the Cox–Ross–Rubinstein model, are considered in [Chapter 3](#), with a description of the passage from discrete to continuous time that prepares the transition to the subsequent chapters.

A simplified presentation of Brownian motion, stochastic integrals, and the associated Itô formula, is given in [Chapter 4](#), with application to stochastic asset price modeling in [Chapter 5](#). The Black–Scholes model is presented from the angle of partial differential equation (PDE) methods in [Chapter 6](#), with the derivation of the Black–Scholes formula by transforming the Black–Scholes PDE into the standard heat equation, which is then solved by a heat kernel argument. The martingale approach to pricing and hedging is then presented in [Chapter 7](#), and complements the PDE approach of [Chapter 6](#) by recovering the Black–Scholes formula via a probabilistic argument. An introduction to stochastic volatility is given in [Chapter 8](#), followed by a presentation of volatility estimation tools including historical, local, and implied volatilities, in [Chapter 9](#). This chapter also contains a comparison of the prices obtained by the Black–Scholes formula with actual option price market data.

Exotic options such as barrier, lookback, and Asian options are treated in [Chapters 11](#), [12](#), and [13](#), respectively, following an introduction to the properties of the maximum of Brownian motion given in [Chapter 10](#). Optimal stopping and exercise, with application to the pricing of American options, are considered in [Chapter 15](#), following the presentation of background material on filtrations and stopping times in [Chapter 14](#). The construction of forward measures by change of numéraire is given in [Chapter 16](#) and is applied to the pricing of interest rate derivatives such as caplets, caps, and swaptions in [Chapter 19](#), after an introduction to bond pricing and to the modeling of forward rates in [Chapters 17](#) and [18](#).

Stochastic calculus with jumps is dealt with in [Chapter 20](#) and is restricted to compound Poisson processes, which only have a finite number of jumps on any bounded interval. Those processes are used for option pricing and hedging in jump models in [Chapter 21](#), in which we mostly focus on risk-minimizing strategies, as markets with jumps are generally incomplete. [Chapter 22](#) contains an elementary introduction to finite difference methods for the numerical solution of PDEs and stochastic differential equations, dealing with the explicit and implicit finite difference schemes for the heat equations and the Black–Scholes PDE, as well as the Euler and Milshtein schemes for SDEs. The text is completed with an appendix containing the needed probabilistic background.

The material in this book has been used for teaching in the Masters of Science in Financial Engineering at City University of Hong Kong and at the Nanyang Technological University in Singapore. The author thanks Nicky van Foreest, Jinlong Guo, Kazuhiro Kojima, Sijian Lin, Panwar Samay, Sandu Ursu, and Ju-Yi Yen for corrections and improvements. The cover graph represents the price map of an up-and-out barrier call (or down-and-out barrier put) option price; see [Chapter 11](#).

Nicolas Privault
2022

Introduction

Modern quantitative finance requires a strong background in fields such as stochastic calculus, optimization, partial differential equations (PDEs) and numerical methods, or even infinite dimensional analysis. In addition, the emergence of new complex financial instruments on the markets makes it necessary to rely on increasingly sophisticated mathematical tools. Not all readers of this book will eventually work in quantitative financial analysis; nevertheless, they may have to interact with quantitative analysts, and becoming familiar with the tools they employ could be an advantage. In addition, despite the availability of readymade financial calculators, it still makes sense to be able oneself to understand, design, and implement such financial algorithms. This can be particularly useful under different types of conditions, including an eventual lack of trust in financial indicators, possible unreliability of expert advice such as buy/sell recommendations, or other factors such as market manipulation. Instead of relying on predictions of stock price movements based on various tools (*e.g.* technical analysis, charting), we acknowledge that predicting the future is a difficult task, and we rely on the efficient market hypothesis. In this framework, the time evolution of the prices of risky assets will be modeled by random walks and stochastic processes.

Historical sketch

We start with a description of some of the main steps, ideas, and individuals that played an important role in the development of the field over the last century.

Robert Brown, botanist, 1828

Brown (1828) observed the movement of pollen particles as described in “A brief account of microscopical observations made in the months of June, July, and August, 1827, on the particles contained in the pollen of plants; and on the general existence of active molecules in organic and inorganic bodies.” *Phil. Mag.* 4, 161–173, 1828.

Figure 1: Two sample paths of one-dimensional Brownian motion.

Philosophical Magazine, first published in 1798, is a journal that publishes articles in the field of condensed matter describing original results, theories and concepts relating to the

structure and properties of crystalline materials, ceramics, polymers, glasses, amorphous films, composites and soft matter.

Albert Einstein, physicist

Einstein received his 1921 Nobel Prize in part for investigations on the theory of Brownian motion: "... in 1905 Einstein founded a kinetic theory to account for this movement", presentation speech by S. Arrhenius, Chairman of the Nobel Committee, December 10, 1922.

Einstein (1905) "Über die von der molekularkinetischen Theorie der Wärme geforderte Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen", *Annalen der Physik* 17.

Louis Bachelier, mathematician, PhD 1900

Bachelier (1900) used Brownian motion for the modeling of stock prices in his PhD thesis "Théorie de la spéculation", *Annales Scientifiques de l'Ecole Normale Supérieure* 3 (17): 21-86, 1900.

Norbert Wiener, mathematician, founder of cybernetics

Wiener is credited, among other fundamental contributions, for the mathematical foundation of Brownian motion, published in 1923. In particular he constructed the Wiener space and Wiener measure on $C_0([0, 1])$ (the space of continuous functions from $[0, 1]$ to $\mathbb{R}$ vanishing at 0).

Wiener (1923) "Differential space", *Journal of Mathematics and Physics of the Massachusetts Institute of Technology*, 2, 131-174, 1923.

Kiyoshi Itô, mathematician, C.F. Gauss Prize 2006

Itô constructed the Itô integral with respect to Brownian motion, cf. Itô, Kiyoshi, Stochastic integral. *Proc. Imp. Acad. Tokyo* 20, (1944), 519–524. He also constructed the stochastic calculus with respect to Brownian motion, which laid the foundation for the development of calculus for random processes, see Itô (1951) "On stochastic differential equations", in *Memoirs of the American Mathematical Society*.

"Renowned math wiz Itô, 93, dies." (The Japan Times, Saturday, November 15, 2008)

Kiyoshi Itô, an internationally renowned mathematician and professor emeritus at Kyoto University died Monday of respiratory failure at a Kyoto hospital, the university said Friday. He was 93. Itô was once dubbed "the most famous Japanese in Wall Street" thanks to his contribution to the founding of financial derivatives theory. He is known for his work on stochastic differential equations and the "Itô Formula", which laid the foundation for the Black and Scholes (1973) model, a key tool for financial engineering. His theory is also widely used in fields like physics and biology.

Paul Samuelson, economist, Nobel Prize 1970

Samuelson (1965) rediscovered Bachelier's ideas and proposed geometric Brownian motion as a model for stock prices. In an interview he stated, "In the early 1950s I was able to locate by chance this unknown Bachelier (1900) book, rotting in the library of the University of Paris, and when I opened it up it was as if a whole new world was laid out before me." We refer to "Rational theory of warrant pricing" by Paul Samuelson, *Industrial Management Review*, p. 13–32, 1965.

In recognition of Bachelier's contribution, the Bachelier Finance Society was started in 1996 and now holds the World Bachelier Finance Congress every two years.

Robert Merton, Myron Scholes, economists

Robert Merton and Myron Scholes shared the 1997 Nobel Prize in economics: "In collaboration with Fisher Black, developed a pioneering formula for the valuation of stock options ... paved the way for economic valuations in many areas ... generated new types of financial instruments and facilitated more efficient risk management in society."*

Black and Scholes (1973) "The Pricing of Options and Corporate Liabilities". Journal of Political Economy 81 (3): 637–654.

The development of options pricing tools contributed greatly to the expansion of option markets and led to development several ventures such as the "Long Term Capital Management" (LTCM), founded in 1994. The fund yielded annualized returns of over 40% in its first years, but registered a loss of US\$4.6 billion in less than four months in 1998, which resulted in its closure in early 2000.

Oldřich Vašíček, economist, 1977

Interest rates behave differently from stock prices, notably due to the phenomenon of mean reversion, and for this reason they are difficult to model using geometric Brownian motion. Vašíček (1977) was the first to suggest a mean-reverting model for stochastic interest rates, based on the Ornstein–Uhlenbeck process, in "An equilibrium characterization of the term structure", Journal of Financial Economics 5: 177–188.

David Heath, Robert Jarrow, Andrew Morton

These authors proposed in 1987 a general framework to model the evolution of (forward) interest rates, known as the Heath–Jarrow–Morton (HJM) model, see Heath et al. (1992) "Bond pricing and the term structure of interest rates: a new methodology for contingent claims valuation", Econometrica, (January 1992), Vol. 60, No. 1, pp 77–105.

Alan Brace, Dariusz Gatarek, Marek Musiela (BGM)

The Brace et al. (1997) model is actually based on geometric Brownian motion, and it is especially useful for the pricing of interest rate derivatives such as interest rate caps and swaptions on the LIBOR market; see "The Market Model of Interest Rate Dynamics". Mathematical Finance Vol. 7, page 127, Blackwell 1997, by Alan Brace, Dariusz Gatarek, Marek Musiela. Although LIBOR rates are being phased out, we will still use this terminology when referring to simple or linear compounded forward rates.

Financial derivatives

The following graphs exhibit a correlation between commodity (oil) prices and an oil-related asset price.

*This has to be put in relation with the modern development of *risk societies*: "societies increasingly preoccupied with the future (and also with safety), which generates the notion of risk" (Wikipedia).

(a) WTI price graph.

(b) Graph of Keppel Corp. stock price

Figure 2: Comparison of WTI *vs* Keppel price graphs.

The study of financial derivatives aims at finding functional relationships between the price of an underlying asset (a company stock price, a commodity price, etc.) and the price of a related financial contract (an option, a financial derivative, etc.).

Option contracts

Early accounts of option contracts can also be found in *The Politics* Aristotle (BCE) by Aristotle (384-322 BCE). Referring to the philosopher Thales of Miletus (c. 624–c. 546 BCE), Aristotle writes:

“He (Thales) knew by his skill in the stars while it was yet winter that there would be a great harvest of olives in the coming year; so, having a little money, he gave *deposits* for the use of all the olive-presses in Chios and Miletus, which he hired at a low price because no one bid against him. When the harvest-time came, and many were wanted all at once and of a sudden, he let them out at any rate which he pleased, and made a quantity of money”.

In the above example, olive oil can be regarded as the underlying asset, while the oil press stands for the financial derivative. Option credit contracts appear to have been used as early as the tenth century by traders in the Mediterranean.

The derivatives market

As of year 2015, the size of the derivatives market was estimated at more than \$1.2 quadrillion,* or more than 10 times the Gross World Product (GWP). See the website <https://stats.bis.org/statx/toc/DER.html> of the Bank for International Settlements (BIS) for up-to-date data on notional amounts outstanding and gross market value.

Next, we move to a description of (European) call and put options, which are at the basis of risk management.

European put option contracts

As previously mentioned, an important concern for the buyer of a stock at time t is whether its price S_T can decline at some future date T . The buyer of the stock may seek protection from a market crash by purchasing a contract that allows him to sell his asset

*One thousand trillion, or one million billion, or 10^{15} .

at time T at a guaranteed price K fixed at time t . This contract is called a put option with strike price K and exercise date T .

Figure 3: Graph of the Hang Seng index—holding a put option might be useful here.

Definition 1. A (European) put option is a contract that gives its holder the right (but not the obligation) to sell a quantity of assets at a predefined price K called the strike price (or exercise price) and at a predefined date T called the maturity.

In case the price S_T falls down below the level K , exercising the contract will give the holder of the option a gain equal to $K - S_T$ in comparison to those who did not subscribe the option contract and have to sell the asset at the market price S_T . In turn, the issuer of the option contract will register a loss also equal to $K - S_T$ (in the absence of transaction costs and other fees).

If S_T is above K , then the holder of the option contract will not exercise the option as he may choose to sell at the price S_T . In this case the profit derived from the option contract is 0.

Two possible scenarios (S_T finishing above K or below K) are illustrated in Figure 4.

Figure 4: Two put option scenarios.

In general, the payoff of a (so-called *European*) put option contract can be written as

$$\phi(S_T) = (K - S_T)^+ := \begin{cases} K - S_T & \text{if } S_T \leq K, \\ 0, & \text{if } S_T \geq K. \end{cases}$$

Figure 5: Payoff function of a put option with strike price $K = 100$.

Example of put option: the buy-back guarantee in currency exchange is a common example of European put option.

Cash settlement vs physical delivery

Physical delivery. In the case of physical delivery, the put option contract issuer will pay the strike price $\$K$ to the option contract holder in exchange for one unit of the risky asset priced S_T .

Cash settlement. In the case of a cash settlement, the put option issuer will satisfy the contract by transferring the amount $C = (K - S_T)^+$ to the option contract holder.

European call option contracts

On the other hand, if the trader aims at buying some stock or commodity, his interest will be in prices not going up, and he might want to purchase a call option, which is a contract allowing him to buy the considered asset at time T at a price not higher than a level K fixed at time t .

Definition 2. A (European) call option is a contract that gives its holder the right (but not the obligation) to purchase a quantity of assets at a predefined price K called the strike price, and at a predefined date T called the maturity.

Here, in the event that S_T goes above K , the buyer of the option contract will register a potential gain equal to $S_T - K$ in comparison to an agent who did not subscribe to the call option.

Two possible scenarios (S_T finishing above K or below K) are illustrated in [Figure 6](#).

In general, the payoff of a (so-called European) call option contract can be written as

$$\phi(S_T) = (S_T - K)^+ := \begin{cases} S_T - K & \text{if } S_T \geq K, \\ 0, & \text{if } S_T \leq K. \end{cases}$$

Figure 6: Two call option scenarios.

According to market practice, options are often divided into a certain number n of *warrants*, the (possibly fractional) quantity n being called the *entitlement ratio*.

Example of call option: the price lock guarantee in online ticket booking is a common example of European *call* option.

Cash settlement vs physical delivery

Physical delivery. In the case of physical delivery, the call option contract issuer will transfer one unit of the risky asset priced S_T to the option contract holder in exchange for the strike price $\$K$. Physical delivery may include physical goods, commodities, or assets such as coffee, airline fuel, or live cattle, see Schroeder and Coffey (2018).

Cash settlement. In the case of a cash settlement, the call option issuer will fulfill the contract by transferring the amount $C = (S_T - K)^+$ to the option contract holder.

Option pricing

In order for an option contract to be fair, the buyer of the option contract should pay a fee (similar to an insurance fee) at the signature of the contract. The computation of this fee is an important issue, which is known as option *pricing*.

Figure 7: Payoff function of a call option with strike price $K = 100$.

Option hedging

The second important issue is that of *hedging*, *i.e.* how to manage a given portfolio in such a way that it contains the required random payoff $(K - S_T)^+$ (for a put option) or $(S_T - K)^+$ (for a call option) at the maturity date T .

Example: Fuel hedging and the four-way zero-collar option

(a) WTI price graph.

(b) Brent price graph.

Figure 8: Brent and WTI price graphs.

```

1 install.packages("Quandl")
2 library(Quandl);library(quantmod)
3 getSymbols("DCOILBRENTU", src="FRED")
4 chartSeries(DCOILBRENTU,up.col="blue",theme="white",name = "BRENT Oil Prices",lwd=5)
5 BRENT = Quandl("FRED/DCOILBRENTU",start_date="2010-01-01", end_date="2015-11-30",type="xts")
6 chartSeries(BRENT,up.col="blue",theme="white",name = "BRENT Oil Prices",lwd=5)
7 getSymbols("WTI", from="2010-01-01", to="2015-11-30")
8 WTI <- Ad(`WTI`)
9 chartSeries(WTI,up.col="blue",theme="white",name = "WTI Oil Prices",lwd=5)

```

The four-way call collar call option requires its holder to purchase the underlying asset (here, airline fuel) at a price specified by the blue curve in Figure 9, when the underlying asset price is represented by the red line.

Figure 9: Price map of a four-way collar option.

The four-way call collar option contract will result into a positive or negative payoff depending on current fuel prices, as illustrated in Figure 10.

Figure 10: Payoff function of a four-way call collar option.

The four-way call collar payoff can be written as a linear combination

$$\phi(S_T) = (K_1 - S_T)^+ - (K_2 - S_T)^+ + (S_T - K_3)^+ - (S_T - K_4)^+$$

of call and put option payoffs with respective strike prices

$$K_1 = 90, \quad K_2 = 100, \quad K_3 = 120, \quad K_4 = 130.$$

Figure 11: Four-way call collar payoff as a combination of call and put options.

Therefore, the four-way call collar option contract can be *synthesized* by:

1. purchasing a *put option* with strike price $K_1 = \$90$,
2. selling (or issuing) a *put option* with strike price $K_2 = \$100$,
3. purchasing a *call option* with strike price $K_3 = \$120$,
4. selling (or issuing) a *call option* with strike price $K_4 = \$130$.

Moreover, the call collar option contract can be made *costless* by adjusting the boundaries K_1, K_2, K_3, K_4 , in which case it becomes a *zero-collar* option.

Example – The one-step 4-5-2 model

We close this introduction with a simplified example of the pricing and hedging technique in a binary model. Consider:

- i) A risky underlying stock valued $S_0 = \$4$ at time $t = 0$, and taking only two possible values

$$S_1 = \begin{cases} \$5 \\ \$2 \end{cases}$$

at time $t = 1$.

- ii) An option contract that promises a claim payoff C whose values are defined contingent to the market data of S_1 as:

$$C := \begin{cases} \$3 & \text{if } S_1 = \$5 \\ \$0 & \text{if } S_1 = \$2. \end{cases}$$

Exercise: Does C represent the payoff of a put option contract? Of a call option contract? If yes, with which strike price K ?

At time $t = 0$ the option contract issuer (or writer) chooses to invest ξ units in the risky asset S , while keeping $\$ \eta$ on our bank account, meaning that we invest a total amount

$$\xi S_0 + \$ \eta \quad \text{at time } t = 0.$$

Here, the amount $\$ \eta$ may be positive or negative, depending on whether it corresponds to savings or to debt and is interpreted as a *liability*.

The following issues can be addressed:

- a) *Hedging:* How to choose the portfolio allocation $(\xi, \$ \eta)$ so that the value

$$\xi S_1 + \$ \eta$$

of the portfolio matches the future payoff C at time $t = 1$?

- b) *Pricing:* How to determine the amount $\xi S_0 + \$ \eta$ to be invested by the option contract issuer in such a portfolio at time $t = 0$?

$S_0 = 4$	$S_1 = 5$ and $C = 3$
	$S_1 = 2$ and $C = 0$

Hedging or replicating the contract means that at time $t = 1$ the portfolio value matches the future payoff C , *i.e.*

$$\xi S_1 + \$ \eta = C.$$

Hedge, then price. This condition can be rewritten as

$$C = \begin{cases} \$3 = \xi \times \$5 + \$\eta & \text{if } S_1 = \$5, \\ \$0 = \xi \times \$2 + \$\eta & \text{if } S_1 = \$2, \end{cases}$$

i.e.

$$\begin{cases} 5\xi + \eta = 3, \\ 2\xi + \eta = 0, \end{cases} \quad \text{which yields} \quad \begin{cases} \xi = 1 \text{ stock}, \\ \$\eta = -\$2. \end{cases}$$

In other words, the option contract issuer purchases 1 (one) unit of the stock S at the price $S_0 = \$4$, and borrows $\$2$ from the bank. The price of the option contract is then given by the portfolio value

$$\xi S_0 + \$\eta = 1 \times \$4 - \$2 = \$2.$$

at time $t = 0$.

This algorithm is scalable and can be extended to recombining binary trees over multiple time steps.

Definition 3. *The arbitrage-free price of the option contract is defined as the initial cost $\xi S_0 + \$\eta$ of the portfolio hedging the claim payoff C .*

Conclusion: in order to deliver the random payoff $C = \begin{cases} \$3 & \text{if } S_1 = \$5 \\ \$0 & \text{if } S_1 = \$2. \end{cases}$ to the option contract holder at time $t = 1$, the option contract issuer (or writer) will:

1. charge $\xi S_0 + \$\eta = \2 (the option contract price) at time $t = 0$,
2. borrow $-\$ \eta = \2 from the bank,
3. invest those $\$2 + \$2 = \$4$ into the purchase of $\xi = 1$ unit of stock valued at $S_0 = \$4$ at time $t = 0$,
4. wait until time $t = 1$ to find that the portfolio value has evolved into

$$C = \begin{cases} \xi \times \$5 + \$\eta = 1 \times \$5 - \$2 = \$3 & \text{if } S_1 = \$5, \\ \xi \times \$2 + \$\eta = 1 \times \$2 - \$2 = 0 & \text{if } S_1 = \$2, \end{cases}$$

so that the option contract and the equality $C = \xi S_1 + \$\eta$ can be fulfilled, allowing the option issuer to break even whatever the evolution of the risky asset price S .

In a *cash settlement*, the stock is sold at the price $S_1 = \$5$ or $S_1 = \$2$, the payoff $C = (S_1 - K)^+ = \$3$ or $\$0$ is issued to the option contract holder, and the loan is refunded with the remaining $\$2$.

In the case of *physical delivery*, $\xi = 1$ share of stock is handed in to the option holder in exchange for the strike price $K = \$2$, which is used to refund the initial $\$2$ loan subscribed by the issuer.

Here, the option contract price $\xi S_0 + \$\eta = \2 is interpreted as the cost of hedging the option. In [Chapters 2](#) and [3](#), we will see that this model is scalable and extends to discrete time.

We note that the initial option contract price of \$2 can be turned to $C = \$3$ (%50 profit) ... or into $C = \$0$ (total ruin).

Thinking further

1) The expected claim payoff at time $t = 1$ is

$$\begin{aligned}\mathbb{E}[C] &= \$3 \times \mathbb{P}(C = \$3) + \$0 \times \mathbb{P}(C = \$0) \\ &= \$3 \times \mathbb{P}(S_1 = \$5).\end{aligned}$$

In absence of arbitrage opportunities (“fair market”), this expected payoff $\mathbb{E}[C]$ should equal the initial amount \$2 invested in the option. In that case we should have

$$\begin{cases} \mathbb{E}[C] = \$3 \times \mathbb{P}(S_1 = \$5) = \$2 \\ \mathbb{P}(S_1 = \$5) + \mathbb{P}(S_1 = \$2) = 1. \end{cases}$$

from which we can *infer* the probabilities

$$\begin{cases} \mathbb{P}(S_1 = \$5) = \frac{2}{3} \\ \mathbb{P}(S_1 = \$2) = \frac{1}{3}, \end{cases} \quad (1)$$

which are called *risk-neutral* probabilities. We see that under the risk-neutral probabilities, the stock S has twice more chances to go up than to go down in a “fair” market.

2) Based on the probabilities (1) we can also compute the expected value $\mathbb{E}[S_1]$ of the stock at time $t = 1$. We find

$$\begin{aligned}\mathbb{E}[S_1] &= \$5 \times \mathbb{P}(S_1 = \$5) + \$2 \times \mathbb{P}(S_1 = \$2) \\ &= \$5 \times \frac{2}{3} + \$2 \times \frac{1}{3} \\ &= \$4 \\ &= S_0.\end{aligned}$$

Here, this means that, on average, no extra profit or loss can be made from an investment on the risky stock, and the probabilities $(2/3, 1/3)$ are termed *risk-neutral* probabilities. In a more realistic model we can assume that the riskless bank account yields an interest rate equal to r , in which case the above analysis is modified by letting $\$ \eta$ become $\$(1+r)\eta$ at time $t = 1$; nevertheless, the main conclusions remain unchanged.

Market-implied probabilities

By matching the theoretical price $\mathbb{E}[C]$ to an actual market price data $\$M$ as

$$\$M = \mathbb{E}[C] = \$3 \times \mathbb{P}(C = \$3) + \$0 \times \mathbb{P}(C = \$0) = \$3 \times \mathbb{P}(S_1 = \$5)$$

we can infer the probabilities

$$\begin{cases} \mathbb{P}(S_1 = \$5) = \frac{\$M}{3} \\ \mathbb{P}(S_1 = \$2) = \frac{3 - \$M}{3}, \end{cases} \quad (2)$$

which are *implied probabilities* estimated from market data, as illustrated in Figure 12. We note that the conditions

$$0 < \mathbb{P}(S_1 = \$5) < 1, \quad 0 < \mathbb{P}(S_1 = \$2) < 1$$

are equivalent to $0 < \$M < 3$, which is consistent with financial intuition in a non-deterministic market.

Figure 12: Implied probabilities.

Implied probabilities can be estimated using *e.g.* binary options; see for example Exercise 3.9.

The *Practitioner* expects a good model to be:

- *Robust* with respect to missing, spurious, or noisy data,
- *Fast* - prices have to be delivered daily in the morning,
- *Easy* to calibrate - parameter estimation,
- *Stable* with respect to re-calibration and the use of new data sets.

Typically, a medium-size bank manages 5,000 options and 10,000 deals daily over 1,000 possible scenarios and dozens of time steps. This can mean a hundred million computations of $\mathbb{E}[C]$ daily, or close to a billion such computations for a large bank.

The *Mathematician* tends to focus on more theoretical features, such as:

- *Elegance*,
- *Sophistication*,
- *Existence* of analytical (closed-form) solutions / error bounds,
- *Significance* to mathematical finance.

This includes:

- *Creating* new payoff functions and structured products,
- *Defining* new models for underlying asset prices,
- *Finding* new ways to compute expectations $\mathbb{E}[C]$ and hedging strategies.

Figure 13: Fifty sample price paths used for the Monte Carlo method.

The methods involved include:

- Monte Carlo methods (60%),
- PDEs and finite differences methods (30%),
- Other analytic methods and approximation methods (10%),

+ AI and Machine Learning techniques.

Book plan

The book plan from [Chapter 1](#) to [Chapter 7](#) is structured in layers that repeat the main concepts (arbitrage, pricing, hedging, risk-neutral measures) in different time scale settings (one-step, discrete-time, continuous-time).

Figure 14: Book plan.
